

Problem 1.

Write a program that simply prints "I am going to love this course" to the screen.

Problem 2.

Write a program that defines two integers, one being the largest 3-digit number and one being the smallest 5-digit number. Then, print these two values, and their sum to the screen.

Problem 3.

Write a program that calculates the final cost of a set of items. For example, if each item costs 1.43 and we need 9 of them. Then, print the final cost.

For example:

```
1 Cost? 1.43
2 How many? 9
3 Total cost is $12.87.
```

First do it by "hard-coding" the numbers. Once you have that working, add the ability to ask the user to input the numbers.

Problem 4.

Write a program that for a temperature in degrees Celsius, prints the equivalent temperature in degrees Fahrenheit (multiply C by 1.8, then add 32).

For example:

```
1 Celsius temperature: 30
2 Fahrenheit equivalent is: 86
```

As with Problem 3, first put the Celsius temperature in your program directly and get it working. Then add the functionality to prompt the user for the Celsius temperature.

Problem 5.

Write a program to evaluate $y = 4x + 3$ for any float number the user may pick. Ask a user to input any x , and then evaluate y , and present the result to two decimal places.

For example:

```
1 Input x: 3.69
2 The value of y = 4x + 3 is 17.76
```
